# Stochastic Processes: Data Analysis and Computer Simulation

## Python programming for beginners

### 3. The Euler method for numerical integration

#### 3.1. Ordinary differential equations (ODE)

##### 1st order ODE

- Consider the following 1st order differential equation.

$$\frac{dy(t)}{dt} = f(y(t), t) \quad (\text{A1})$$

- Assume that the initial conditions are  $y = y_0$  at time  $t = t_0$ .
- We need to determine  $y(t)$ , for any  $t \geq t_0$ .

##### Formal solution

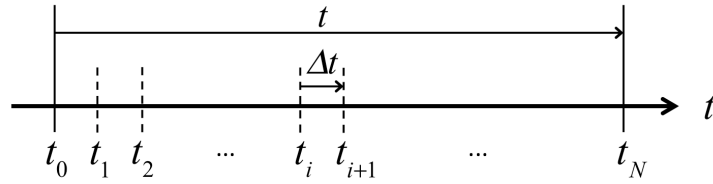

- Integrate Eq.(A1) over time, from  $0 \rightarrow t$ , to obtain the formal solution for  $y(t)$

$$y(t) = y_0 + \int_{t_0}^t dt' f(y(t'), t') \quad (\text{A2})$$

#### 3.2. Numerical calculation

## Discretization

- Divide the total time span  $t_0 \rightarrow t$  into  $N$  equally spaced segments, each describing a time increment  $\Delta t$ .

$$t_i \equiv t_0 + i\Delta t, \quad y_i \equiv y(t_i), \quad f_i \equiv f(t_i, y(t_i)) \quad (\text{A3})$$

## Advancing the solution forward a small step $\Delta t$

- Integrate Eq.(A1) over a small time interval, from  $t_i \rightarrow t_{i+1}(= t_i + \Delta t)$ ,

$$y_{i+1} = y_i + \int_{t_i}^{t_{i+1}} dt' f(y(t'), t') \quad (\text{A3})$$

$$= y_i + \int_0^{\Delta t} d\tau f(y(t_i + \tau), t_i + \tau) \quad (\tau \equiv t' - t_i) \quad (\text{A4})$$

$$= y_i + \int_0^{\Delta t} d\tau [f_i + \mathcal{O}(\tau) + \mathcal{O}(\tau^2) + \dots] \quad (\text{A5})$$

$$= y_i + [\tau f_i + \mathcal{O}(\tau^2) + \mathcal{O}(\tau^3) + \dots]_0^{\Delta t} \quad (\text{A6})$$

$$= y_i + \Delta t f_i + \mathcal{O}(\Delta t^2) + \mathcal{O}(\Delta t^3) + \dots \quad (\text{A7})$$

## Euler method

- Difference equation  $\rightarrow$  1st order in  $\Delta t$

$$y_{i+1} = y_i + \Delta t f_i \quad (\text{A8})$$

- Simulation procedure  $\rightarrow$  Explicit method

$$y_0, f_0 \xrightarrow[\Delta t]{\text{Eq.(A8)}} y_1, f_1 \xrightarrow[\Delta t]{\text{Eq.(A8)}} \dots y_i, f_i \dots \xrightarrow[\Delta t]{\text{Eq.(A8)}} y_N, f_N \quad (\text{A9})$$

- Forward difference approximation (1st order)

$$\left. \frac{dy(t)}{dt} \right|_{t=t_i} \simeq \frac{y_{i+1} - y_i}{\Delta t} \quad (\text{A10})$$

## Leapfrog method

- Central difference approximation

$$\left. \frac{dy(t)}{dt} \right|_{t=t_i} \simeq \frac{y_{i+1} - y_{i-1}}{2\Delta t} \quad (\text{A11})$$

- Difference equation, Substitute Eq.(A11) in Eq.(A1)

$$y_{i+1} = y_{i-1} + 2\Delta t f_i \quad (\text{A12})$$

- Simulation procedure  $\rightarrow$  Explicit method

$$y_{-1}, f_0 \xrightarrow[2\Delta t]{\text{Eq.(A11)}} y_1, f_2 \xrightarrow[2\Delta t]{\text{Eq.(A11)}} \dots y_i, f_{i+1} \dots \xrightarrow[2\Delta t]{\text{Eq.(A11)}} y_N \quad (\text{A13})$$

$$y_0, f_1 \xrightarrow[2\Delta t]{\text{Eq.(A11)}} y_2, f_3 \dots \xrightarrow[2\Delta t]{\text{Eq.(A11)}} y_{N-1}, f_N \quad (\text{A14})$$

## Runge-Kutta (2nd)

- Difference equation

$$y'_{i+\frac{1}{2}} = y_i + \frac{1}{2} \Delta t f_i \quad (\text{Euler}) \quad (\text{A15})$$

$$y_{i+1} = y_i + \Delta t f(t_{i+\frac{1}{2}}, y'_{i+\frac{1}{2}}) = y_i + \Delta t f'_{i+\frac{1}{2}} \quad (\text{Leapfrog}) \quad (\text{A16})$$

- Simulation procedure → Explicit method

$$\begin{array}{lcl}
 y_0, f_0 & \xrightarrow[\frac{1}{2} \Delta t]{\text{Eq.(A15)}} & y'_{\frac{1}{2}}, f'_{\frac{1}{2}} \\
 & \xrightarrow[\frac{1}{2} \Delta t]{\text{Eq.(A15)}} & y_1, f_1 \\
 & \xrightarrow[\frac{1}{2} \Delta t]{\text{Eq.(A15)}} & y'_{1+\frac{1}{2}}, f'_{1+\frac{1}{2}} \\
 & \xrightarrow[\frac{1}{2} \Delta t]{\text{Eq.(A15)}} & \dots \\
 & \xrightarrow[\frac{1}{2} \Delta t]{\text{Eq.(A15)}} & y'_{N-\frac{1}{2}}, f'_{N-\frac{1}{2}} \\
 y_0, f'_{\frac{1}{2}} & \xrightarrow[\Delta t]{\text{Eq.(A16)}} & y_1, f'_{1+\frac{1}{2}} \\
 & \xrightarrow[\Delta t]{\text{Eq.(A16)}} & \dots \\
 & \xrightarrow[\Delta t]{\text{Eq.(A16)}} & y_i, f'_{i+\frac{1}{2}} \\
 & \xrightarrow[\Delta t]{\text{Eq.(A16)}} & \dots \\
 & \xrightarrow[\Delta t]{\text{Eq.(A16)}} & y_N
 \end{array} \quad (\text{A17})$$

## Runge-Kutta (4th)

- Difference equation

$$y'_{i+\frac{1}{2}} = y_i + \frac{\Delta t}{2} f_i, \quad f'_{i+\frac{1}{2}} = f(y'_{i+\frac{1}{2}}, t_{i+\frac{1}{2}}) \quad (\text{A18})$$

$$y''_{i+\frac{1}{2}} = y_i + \frac{\Delta t}{2} f'_i, \quad f''_{i+\frac{1}{2}} = f(y''_{i+\frac{1}{2}}, t_{i+\frac{1}{2}}) \quad (\text{A19})$$

$$y'''_{i+1} = y_i + \Delta t f''_{i+\frac{1}{2}}, \quad f'''_{i+1} = f(y'''_{i+1}, t_{i+1}) \quad (\text{A20})$$

$$y_{i+1} = y_i + \frac{1}{6} \Delta t \left[ f_i + 2f'_{i+\frac{1}{2}} + 2f''_{i+\frac{1}{2}} + f'''_{i+1} \right] \quad (\text{A21})$$

## 3.3. Try the Euler method using Python

### A very simple problem

- Numerically solve the following differential equation and determine  $y(t)$  for  $0 \leq t \leq 10$  with the initial condition  $y = 1$  at  $t = 0$ . Then compare it with the analytical solution  $y = \exp(-t)$ .

$$\frac{dy(t)}{dt} = -y(t) \quad (\text{A22})$$

```

In [1]: % matplotlib inline
import numpy as np          # import numpy library as np
import matplotlib.pyplot as plt # import pyplot library as plt
plt.style.use('ggplot')     # use "ggplot" style for graphs

```

```
In [2]: # Euler method
dt, tmin, tmax = 0.1, 0.0, 10.0 # set \Delta t, t0, tmax
step=int((tmax-tmin)/dt)
# create array t from tmin to tmax with equal interval dt
t = np.linspace(tmin,tmax,step)
y = np.zeros(step) # initialize array y as all 0
ya = np.exp(-t) # analytical solution y=exp(-t)
plt.plot(t,ya,label='Exact',lw=5) # plot y vs. t (analytical)
y[0]=1.0 # initial condition
for i in range(step-1):
    y[i+1]=y[i]-dt*y[i] # Euler method Eq.(A8)
plt.plot(t,y,ls='--',lw=3,label='Numerical') # plot y vs t (numerical)
plt.plot(t,y/ya,lw=3,label='Ratio') # plot y/ya vs. t
plt.legend() #display legends
plt.show() #display plots
```
